

Testing the basic use of SemiXML

Introduction

SemiXML is a library of modules which translate an sxml into a XML based language. For example Html, Soap, Docbook or your own XML language. There are several syntactic constructs which look very much the same as the XML language.

The code below will test a simple top level structure.

```
A one liner
```

```
$st [ ]
```

```
This should translate into
```

```
<st/>
```

We need to write a convenience routine to call the parser several times from the tests. This way we keep the tests simple.

0

Plain top level elements

First a few tests to generate top level elements

Basic nesting

Nesting is done by specifying other tags in the body of a tag.
